

Crystalline Rare-Earth-doped Sesquioxide PLD-Films on alpha-Alumina

Filesize: 6.22 MB

Reviews

This ebook is very gripping and fascinating. Sure, it is engage in, nevertheless an amazing and interesting literature. It is extremely difficult to leave it before concluding, once you begin to read the book.

(Ms. Ora Buckridge)

CRYSTALLINE RARE-EARTH-DOPED SESQUIOXIDE PLD-FILMS ON ALPHA-ALUMINIA

Cuvillier Verlag Jun 2004, 2004. Taschenbuch. Condition: Neu. Neuware - The development of integrated optical devices demands the fabrication of high-quality optically active thin films. This work focuses on thin sesquioxide films, which are promising because the sesquioxides are well-known hosts for rare-earth-ions, leading to luminescent materials and solid-state lasers with superior mechanical and thermal properties (e. g. low phonon energies, large thermal conductivity).Optical quality crystalline thin films of rare-earth-doped sesquioxides (yttria, lutetia, and scandia) have been grown by the pulsed laser deposition (PLD) technique on single-crystal (0001) α -alumina substrates. Alumina substrates offer a lattice constant that matches that of cubic Y₂O₃ in the β 111± direction very well. Using Lu₂O₃ and Sc₂O₃, the mismatch of 4.8% related to Y₂O₃ on alumina substrates can be considerably reduced leading to the production of films with less dislocations.The crystal structure of these films (thicknesses from 1 nm to 500 nm) was determined by X-ray diffraction (XRD) and surface X-ray diffraction (SXRD) analysis. These measurements show that the films were textured along the β 111± direction, however with a small polycrystalline component, which is negligible in thick films. Using Rutherford backscattering analysis (RBS), the correct stoichiometric composition of the films could be proved. At optimum growth conditions, epitaxial growth of Y₂O₃ along the β 111± direction on the (0001) α -Al₂O₃ was experimentally verified by the observation of channelling in the RBS experiments.The surface morphology of the thin films has been studied using atomic force microscopy (AFM). While amorphous films have no defined surface structure, crystalline films show a triangular surface morphology, which is attributed to the β 111± growth direction. The same structure is observed along the (111) cleavage of an yttria bulk crystal. Thin films with a mean thickness of 5 nm have no completely covered surface, but show island growth, where the shape of the...
